Preauthorization is not required.

The following protocol contains medical necessity criteria that apply for this service. The criteria are also applicable to services provided in the local Medicare Advantage operating area for those members, unless separate Medicare Advantage criteria are indicated. If the criteria are not met, reimbursement will be denied and the patient cannot be billed. Please note that payment for covered services is subject to eligibility and the limitations noted in the patient’s contract at the time the services are rendered.

A ventricular assist device (VAD) is a mechanical support attached to the native heart and vessels to augment cardiac output. The total artificial heart (TAH) replaces the native ventricles and is attached to the pulmonary artery and aorta; the native heart is typically removed. Both the VAD and TAH may be used as a bridge to heart transplantation or as destination therapy in those not candidates for transplantation. The VAD has also been used as a bridge to recovery in patients with reversible conditions affecting cardiac output.

SUMMARY OF EVIDENCE

VENTRICULAR ASSIST DEVICE

For individuals who have end-stage heart failure who receive a VAD as a bridge to transplant, the evidence includes single-arm trials and observational studies. Relevant outcomes are overall survival, symptoms, functional outcomes, QOL, and treatment-related mortality and morbidity. There is a substantial body of evidence from clinical trials and observational studies supporting implantable VADs as a bridge to transplant in patients with end-stage heart failure, possibly improving mortality as well as QOL. These studies have reported that substantial numbers of patients have survived to transplant in situations in which survival would not be otherwise expected. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcome.

For individuals who have end-stage heart failure who receive a VAD as destination therapy, the evidence includes a trial and multiple single-arm studies. Relevant outcomes are overall survival, symptoms, functional outcomes, QOL, and treatment-related mortality and morbidity. A well-designed trial, with two years of follow-up data, has demonstrated an advantage of implantable VADs as destination therapy for patients ineligible for heart transplant. Despite an increase in adverse events, both mortality and QOL appear to be improved for these patients. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcome.
TOTAL ARTIFICIAL HEART

For individuals who have end-stage heart failure who receive a TAH as a bridge to transplant, the evidence includes case series. Relevant outcomes are overall survival, symptoms, functional outcomes, QOL, and treatment-related mortality and morbidity. Compared with VADs, the evidence for TAHs in these settings is less robust. However, based on the lack of medical or surgical options for these patients and the evidence case series provide, TAH is likely to improve outcomes for a carefully selected population with end-stage biventricular heart failure awaiting transplant who are not appropriate candidates for a left VAD. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcome.

For individuals who have end-stage heart failure who receive a TAH as destination therapy, the evidence includes two case series. Relevant outcomes are overall survival, symptoms, functional outcomes, QOL, and treatment-related mortality and morbidity. The body of evidence for TAHs as destination therapy is too limited to draw conclusions. The evidence is insufficient to determine the effects of the technology on health outcomes.

PERCUTANEOUS VENTRICULAR ASSIST DEVICE

For individuals with cardiogenic shock or who undergo high-risk cardiac procedures who receive a pVAD, the evidence includes randomized controlled trials. Relevant outcomes are overall survival, symptoms, morbid events, functional outcomes, QOL, and treatment-related mortality and morbidity. Four randomized controlled trials of pVAD vs. IABP for patients in cardiogenic shock failed to demonstrate a mortality benefit and reported higher complication rates associated with pVAD use. Another randomized controlled trial comparing pVAD with IABP as an adjunct to high-risk percutaneous coronary interventions was terminated early due to futility; analysis of enrolled subjects did not demonstrate significant improvements in the pVAD group. The evidence is insufficient to determine the effects of the technology on health outcomes.

For individuals with cardiogenic shock refractory to IABP who receive a pVAD, the evidence includes case series. Relevant outcomes are overall survival, symptoms, morbid events, functional outcomes, QOL, and treatment-related mortality and morbidity. Case series of patients with cardiogenic shock refractory to IABP have reported improved hemodynamic parameters following pVAD placement. However, these uncontrolled series do not provide evidence that pVADs improve mortality, and high rates of complications have been reported with pVAD use. The evidence is insufficient to determine the effects of the technology on health outcomes.

POLICY

BRIDGE TO TRANSPLANTATION

Implantable ventricular assist devices (VADs) with Food and Drug Administration (FDA) approval or clearance may be considered medically necessary as a bridge to heart transplantation for patients who are currently listed as heart transplantation candidates and not expected to survive until a donor heart can be obtained, or are undergoing evaluation to determine candidacy for heart transplantation.

Implantable VADs with FDA approval or clearance, including humanitarian device exemptions, may be considered medically necessary as a bridge to heart transplantation in children 16 years old or younger who are currently listed as heart transplantation candidates and not expected to survive until a donor heart can be obtained, or are undergoing evaluation to determine candidacy for heart transplantation.

Total artificial hearts (TAHs) with FDA-approved devices may be considered medically necessary as a bridge to heart transplantation for patients with biventricular failure who have no other reasonable medical or surgical treatment options, who are ineligible for other univentricular or biventricular support devices, and are currently listed as heart transplantation candidates or are undergoing evaluation to determine candidacy for heart transplantation, and not expected to survive until a donor heart can be obtained.
DESTINATION THERAPY

Implantable VADs with FDA approval or clearance may be considered **medically necessary** as destination therapy with end-stage heart failure patients who are ineligible for human heart transplant and who meet the following REMATCH Study criteria:

- New York Heart Association (NYHA) class IV heart failure for 60 or more days, OR patients in NYHA class III or IV for 28 days, received 14 or more days of support with intra-aortic balloon pump or dependent on intravenous inotropic agents, with two failed weaning attempts.

In addition, patients must not be candidates for human heart transplant for one or more of the following reasons:

- Age greater than 65 years; OR
- Insulin-dependent diabetes mellitus with end-organ damage; OR
- Chronic renal failure (serum creatinine greater than 2.5 mg/dL for 90 or more days); OR
- Presence of other clinically significant condition.

POSTCARDIOTOMY SETTING/BRIDGE TO RECOVERY

- Implantable VADs with FDA approval or clearance may be considered **medically necessary** in the postcardiotomy setting in patients who are unable to be weaned off cardiopulmonary bypass

OTHER INDICATIONS

Other applications of implantable VADs or TAHs are considered **investigational**, including, but not limited to, the use of TAHs as destination therapy. The use of non-FDA approved or cleared implantable VADs or TAHs is considered **investigational**.

Percutaneous VADs are considered **investigational** for all indications.

POLICY GUIDELINES

Only two VADs have approval from the U.S. Food and Drug Administration (FDA) for the pediatric population. The DeBakey VAD® Child device and the Berlin Heart EXCOR Pediatric VAD have FDA approval through the humanitarian device exemption (HDE) process. The DeBakey VAD is indicated for use in children ages five to 16 years who are awaiting a heart transplant (i.e., a bridge to transplant) while the Berlin Heart EXCOR VAD is indicated for children with severe isolated left ventricular or biventricular dysfunction who are candidates for cardiac transplant and require circulatory support.

In general, candidates for bridge-to-transplant implantable VADs are those who are considered appropriate heart transplant candidates but who are unlikely to survive the waiting period until a human heart donor is available. Some studies have included the following hemodynamic selection criteria: either a left atrial pressure of 20 mm Hg or a cardiac index of less than 2.0 L/min/m while receiving maximal medical support. Patients with VADs are classified by the United Network for Organ Sharing as Status I (i.e., persons who are most ill and are considered the highest priority for transplant).

The median duration for time on the device is between 20 and 120 days.

Contraindications for bridge to transplant VADs and TAHs include conditions that would generally exclude patients for heart transplant. Such conditions are chronic irreversible hepatic, renal, or respiratory failure; systemic infection; coagulation disorders and inadequate psychosocial support. Due to potential problems with
adequate function of the VAD or TAH, implantation is also contraindicated in patients with uncorrected valvular disease. See also the Heart Transplant Protocol for further discussion of heart transplant candidacy.

In addition, patients must have sufficient space in the thorax and/or abdominal cavity for the device. In the case of the CardioWest™ temporary Total Artificial Heart, this excludes patients with body surface areas less than 1.7 m² or who have a distance between the sternum and 10th anterior rib of less than 10 cm as measured by computed tomography scan.

**MEDICARE ADVANTAGE**

**VADs**

VADs are medically necessary postcardiotomy (following open-heart surgery). They must have received approval from the Food and Drug Administration (FDA) for that purpose, and they are used according to the FDA-approved labeling instructions.

VADs are medically necessary as bridge-to-transplant. They must have received approval from the FDA for that purpose, and be used according to the FDA-approved labeling instructions. All of the following criteria must also be met in order for a VAD to be medically necessary as a bridge-to-transplant:

a. The patient is approved for heart transplantation by a Medicare-approved heart transplant center and is active on the Organ Procurement and Transplantation Network (OPTN) heart transplant waitlist,

b. The implanting site, if different than the Medicare-approved transplant center, must receive written permission from the Medicare-approved heart transplant center under which the patient is listed prior to implantation of the VAD.

VADs used for destination therapy are medically necessary only if they have received approval from the FDA for that purpose, and the device is used according to the FDA-approved labeling instructions.

VADs are medically necessary for patients who have chronic end-stage heart failure (New York Heart Association Class IV end-stage left ventricular failure) who are not candidates for heart transplantation, and meet all of the following conditions:

a. Have failed to respond to optimal medical management (including beta-blockers and ACE inhibitors if tolerated) for 45 of the last 60 days, or have been balloon pump-dependent for seven days, or IV (intravenous) inotrope-dependent for 14 days; and,

b. Have a left ventricular ejection fraction (LVEF) less than 25%, and,

c. Have demonstrated functional limitation with a peak oxygen consumption of 14 ml/kg/min or less unless balloon pump- or inotrope-dependent or physically unable to perform the test.

**ARTIFICIAL HEARTS**

An artificial heart may have potential to be covered when performed under coverage with evidence development (CED) for the following indications:

1) bridge to transplant (BTT).

2) destination therapy (DT)
MEDICARE ADVANTAGE POLICY GUIDELINES

FACILITY CRITERIA

Facilities which are approved to provide VAD as destination therapy are listed at this web site: https://www.cms.gov/Medicare/Medicare-General-Information/MedicareApprovedFacilities/VAD-Destination-Therapy-Facilities.html.

Prospective VAD recipients must receive all information and support necessary to participate in shared decision making and to provide appropriate informed consent.

BACKGROUND

HEART FAILURE

Heart failure may be the consequence of a number of differing etiologies, including ischemic heart disease, cardiomyopathy, congenital heart defects, or rejection of a heart transplant. The reduction of cardiac output is considered to be severe when systemic circulation cannot meet the body’s needs under minimal exertion. Heart transplantation improves quality of life and has survival rates at one, five, and 10 years of 88%, 74%, and 55%, respectively. The number of candidates for transplants exceeds supply of donor organs; thus the interest in the development of mechanical devices.

Treatment

Total Artificial Hearts

Initial research into mechanical assistance for the heart focused on the TAH, a biventricular device that completely replaces the function of the diseased heart. An internal battery required frequent recharging from an external power source. Many systems use a percutaneous power line, but a transcutaneous power-transfer coil allows for a system without lines traversing the skin, possibly reducing the risk of infection. Because the native heart must be removed, failure of the device is synonymous with cardiac death.

A fully bioprosthetic TAH, which is fully implanted in the pericardial sac and is electrohydraulically actuated, has been developed and tested in two patients but is currently experimental.

Ventricular Assist Devices

Implantable VADs are attached to the native heart, which may have enough residual capacity to withstand a device failure in the short term. In reversible heart failure conditions, the native heart may regain some function, and weaning and explanting of the mechanical support system after months of use has been described. VADs can be classified as internal or external, electrically or pneumatically powered, and pulsatile or continuous-flow. Initial devices were pulsatile, mimicking the action of a beating heart. More recent devices may use a pump, which provides continuous-flow. Continuous devices may move blood in rotary or axial flow.

At least one VAD system developed is miniaturized and generates an artificial pulse, the HeartMate 3 Left Ventricular Assist System.

Surgically implanted VADs represent a method of providing mechanical circulatory support for patients not expected to survive until a donor heart becomes available for transplant or for whom transplantation is contraindicated or unavailable. VADs are most commonly used to support the left ventricle, but right ventricular and biventricular devices may be used. The device is larger than most native hearts, and therefore the size of the patient is an important consideration; the pump may be implanted in the thorax or abdomen or remain external to the body. Inflow to the device is attached to the apex of the failed ventricle, while outflow is attached to the corresponding great artery (aorta for left ventricle, pulmonary artery for right ventricle). A small portion of
ventricular wall is removed for insertion of the outflow tube; extensive cardiotomy affecting the ventricular wall may preclude VAD use.

*Percutaneous VADs*

Devices in which most of the system’s components are external to the body are for short-term use (six hours to 14 days) only, due to the increased risk of infection and need for careful, in-hospital monitoring. Some circulatory assist devices are placed percutaneously (i.e., are not implanted). They may be referred to as percutaneous VADs (pVADs). A pVAD is placed through the femoral artery. Two different pVADs have been developed, the TandemHeart and the Impella device. In the TandemHeart system, a catheter is introduced through the femoral vein and passed into the left atrium via transseptal puncture. Oxygenated blood is then pumped from the left atrium into the arterial system via the femoral artery. The Impella device is introduced through a femoral artery catheter. In this device, a small pump is contained within the catheter placed into the left ventricle. Blood is pumped from the left ventricle, through the device, and into the ascending aorta. Adverse events associated with pVAD include access-site complications such as bleeding, aneurysms, or leg ischemia. Cardiovascular complications can also occur, such as perforation, myocardial infarction, stroke, and arrhythmias.

There are several situations in which pVADs may be beneficial: (1) cardiogenic shock that is refractory to medications and intra-aortic balloon pump, (2) cardiogenic shock as an alternative to intra-aortic balloon pump, and (3) invasive cardiac procedures in high-risk patients who need circulatory support.

Intra-aortic balloon pumps are outside the scope of this protocol.

**REGULATORY STATUS**

A number of mechanical circulatory support devices have been approved or cleared for marketing by the U.S. Food and Drug Administration (FDA). These devices are summarized in Table 1 and discussed in the following sections.

| Table 1. Available Mechanical Circulatory Support Devices |
|------------------|------------------|------------------|------------------|------------------|
| **Device**       | **Manufacturer** | **Date of Initial Approval** | **Method of FDA Clearance** | **Indication**      |
| VADs             |                  |                  |                  |                  |
| Thoratec® IVAD   | Thoratec         | Aug 2004         | PMA supplement   | Bridge to transplant and postcardiomy |
| DeBakey VAD® Child | MicroMed       | Feb 2004         | HDE              | Bridge to transplant in children five-16 years of age |
| HeartMate II®    | Thoratec         | Apr 2008         | PMA              | Bridge to transplant and destination |
| CentriMag®       | Levitronix (now Thoratec) | Oct 2008 | HDE | Postcardiomy |
| Berlin Heart EXCOR® Pediatric VAD | Berlin        | Dec 2011         | HDE              | Bridge to transplant |
| HeartWare® Ventricular Assist System | HeartWare | Dec 2012 | PMA | Bridge to transplant |
| pVADs            |                  |                  |                  |                  |
| Impella®         | Abiomed          | May 2008         | 510(k)           | Partial circulatory support using extracorporeal bypass control unit for ≤ six hours |
| TandemHeart®     | Cardiac Assist   | Sep 2005         | 510(k)           | Temporary left ventricular bypass of ≤ six hours |

FDA: U.S. Food and Drug Administration; HDE: humanitarian device exemption; PMA: premarket approval; pVAD: percutaneous ventricular assist devices; VAD: ventricular assist devices.
TOTAL ARTIFICIAL HEART

In October 2004, the temporary CardioWest™ Total Artificial Heart (SynCardia Systems, Tucson, AZ) was approved by the FDA through the premarket approval (PMA) process for use as a bridge to transplant in cardiac transplant-eligible candidates at risk of imminent death from biventricular failure. This device is also intended for use inside the hospital. In April 2010, FDA approved a name change to SynCardia Temporary Total Artificial Heart. FDA product code: LOZ.

In September 2006, the AbioCor® Implantable Replacement Heart System (Abiomed, Danvers, MA) was approved by FDA through the HDE process for use in severe biventricular end-stage heart disease patients who are not cardiac transplant candidates and who:

- are younger than 75 years of age;
- require multiple inotropic support;
- are not treatable by left VAD destination therapy; and
- are not weanable from biventricular support if on such support.

In addition to meeting other criteria, patients who are candidates for the AbioCor® TAH must undergo a screening process to determine if their chest volume is large enough to hold the device. The device is too large for approximately 90% of women and for many men. FDA HDE: H040006.

VENTRICULAR ASSIST DEVICES

In December 1995, the Thoratec® Ventricular Assist Device System (Thoratec Corp., Pleasanton, CA) was approved by FDA through the PMA process for use as a bridge to transplantation in patients suffering from end-stage heart failure. The patient should meet all of the following criteria:

- candidate for cardiac transplantation,
- imminent risk of dying before donor heart procurement, and
- dependence on, or incomplete response to, continuous vasopressor support.

In May 1998, supplemental approval for this device was given for the indication for postcardiotomy patients unable to be weaned from cardiopulmonary bypass. In June 2001, supplemental approval was given for a portable external driver to permit excursions within a two-hour travel radius of the hospital when accompanied by a trained caregiver. In November 2003, supplemental approval was given to market the device as Thoratec® Paracorporeal VAD. In August 2004, supplemental approval was given to a modified device to be marketed as the Thoratec® Implantable VAD for the same indications. In January 2008, supplemental approval was given to rescind Paracorporeal VAD use.

In February 2004, the DeBakey VAD® Child pump was approved by FDA through the HDE process for both home and hospital use for children between the ages of five and 16 years who have end-stage ventricular failure requiring temporary mechanical blood circulation until a heart transplant is performed.

In April 2008, the continuous-flow HeartMate® II LVAS device (Thoratec, Pleasanton, CA) was approved by FDA through the PMA process for use as a bridge to transplantation in cardiac transplant candidates at risk of imminent death from nonreversible left ventricular failure. The HeartMate® II LVAS device is intended for use both inside and outside the hospital. In January 2010, the device received the added indication as destination therapy for use in patients with New York Heart Association class IIIb or IV end-stage left ventricular failure who have received optimal medical therapy for at least 45 of the last 60 days and are not candidates for cardiac transplantation.
In October 2008, device CentriMag® Right Ventricular Assist Device (Levitronix, Zurich) was approved by FDA under the HDE process to provide temporary circulatory support for up to 14 days for patients in cardiogenic shock due to acute right-sided heart failure.

In December 2011, the Berlin Heart EXCOR® Pediatric VAD was approved by FDA under the HDE for pediatric patients with severe isolated left ventricular or biventricular dysfunction who are candidates for cardiac transplant and require circulatory support.

In December 2012, FDA approved the HeartWare® Ventricular Assist System (HeartWare, Miami Lakes, FL) through the PMA process. The device is approved as a bridge to cardiac transplantation in patients at risk for death from refractory end-stage left ventricular heart failure.

FDA product code: DSQ.

PERCUTANEOUS VADs (CIRCULATORY ASSIST DEVICES)

In May 2008, the Impella® Recover LP 2.5 Percutaneous Cardiac Support System (Abiomed, Aachen, Germany) was cleared for marketing by FDA through the 510(k) process for short-term (less than six hours) use in patients requiring circulatory support.

In March 2015, the Impella 2.5 System received approval through the PMA process for temporary ventricular support during high-risk percutaneous coronary interventions.

The TandemHeart® (Cardiac Assist, Pittsburgh) received a similar 510(k) approval for short-term circulatory support in September 2005. FDA product code: KFM.

Several other devices are in clinical trials or awaiting FDA review.
